February 15, 1937

MILK PRODUCTION: Milk production in the United States on February 1 appears to have been one percent greater than at the same season last year, much of the increase being due to the less severe weather prevailing in important dairy States. The number of milk cows on farms was about 1 1/2 percent less than the number a year ago, but daily production per cow, as reported by Crop Correspondents, was between 2 and 3 percent greater.

Due largely to differences in weather conditions, feed supplies and prices, the various sections of the country differ markedly in current trend of production of dairy products. In the Northeast the number of cows is increasing, farmers are feeding about the usual quantity of grain and, with unusually mild weather, production per cow on the first of February was the highest for that date since 1931. While production did not increase as rapidly during January as it did last year, production per cow on February 1 was still several percent above the 10-year average for the date.

Towards the West, current conditions appear progressively less favorable for dairying. From Ohio westward to Wisconsin, inclusive, there has been only a nominal decrease in milk cows, but grain feeding is rather light. Even with favorable weather through January, the reported production per cow on February 1, while much higher than at the same season in any of the three previous seasons, was not quite up to the 1925-1934 average.

In the West North Central States <sup>where</sup> feed supplies are short, farmers were feeding their milk cows only about two-thirds as much grain per head as at that time last year, and with cold weather and deep snow further reducing the output, the daily production per milk cow was reported slightly lower than the low production a year ago and lower than on comparable dates in any of the last 10 years with the exception of 1935, when feed supplies in this area were even more seriously short. In this group of States, the estimated number of milk cows on farms on January 1 showed a reduction of about 4 percent during 1936, and the number of heifers and heifer calves being saved for milk cows is unusually small.

In most of the South, except in Maryland, Delaware, Florida and Texas, the number of milk cows and of young stock of dairy breeding show a slight but general decline, and feeding is moderately light. Production per cow ranges from about average in the East to substantially below average in the Western Cotton Belt.

In the Western States, the extreme cold caused a sharp reduction in milk production during January, and even though farmers in some States were feeding grain rather liberally on February 1, the reported production per cow in the area was 3 percent below the 10-year average for February 1 and lower than on the same date in any of the preceding 10 years, except 1934. In some States, chiefly California, Idaho, and Colorado, the number of milk cows and heifers increased during 1936, but these increases were about offset by further heavy liquidation of milk cows and young stock in Montana where the drought was most severe, and by moderate reductions in cows in Washington and Oregon.

For the United States as a whole, the average milk production per cow in herds kept by crop correspondents on February 1 was 11.90 pounds compared with 11.60 pounds on February 1, 1936, 11.16 pounds February 1, 1935, and a 1925-34 average of 12.43 pounds for February 1. In the same herds, 65.6 percent of the milk cows were reported milked on February 1 this year compared to 65.4 percent last February, and 65.2 on February 1 two years ago. Grains and concentrates fed per milk cow averaged 3.89 pounds daily in these herds on February 1, compared to 4.54 pounds a year ago, 3.50 pounds 2 years ago (after the drought of 1934) and an average of 4.74 pounds on February 1 during the three preceding years.

1/ Averages per cow computed from answers to question, "How many pounds of grain (including mill feeds and concentrates) were fed yesterday to milk cows on your farm or ranch."

2/ Averages obtained by dividing the reported daily milk production of herds kept by reporters by the total number of milk cows (in milk or dry) in these herds. The regional averages shown were based in part on records from less important dairy States not shown separately, as follows: South Atlantic, Delaware, Georgia, Florida; South Central, Alabama, Louisiana; Western, New Mexico, Arizona, Utah, Nevada.

1/Value per head derived by dividing total value by total number.

Total value represents sum of values by age groups.
